

# 4

## Displaying Data from Multiple Tables

# Objectives

**After completing this lesson, you should be able to do the following:**

- **Write `SELECT` statements to access data from more than one table using equality and nonequality joins**
- **View data that generally does not meet a join condition by using outer joins**
- **Join a table to itself by using a self join**

# Cartesian Products

- **A Cartesian product is formed when:**
  - **A join condition is omitted**
  - **A join condition is invalid**
  - **All rows in the first table are joined to all rows in the second table**
- **To avoid a Cartesian product, always include a valid join condition in a WHERE clause.**

# Types of Joins

## Oracle Proprietary Joins (8i and prior):

- Equijoin
- Non-equijoin
- Outer join
- Self join

## SQL: 1999 Compliant Joins:

- Cross joins
- Natural joins
- Using clause
- Full or two sided outer joins
- Arbitrary join conditions for outer joins

# Joining Tables Using Oracle Syntax

Use a join to query data from more than one table.

```
SELECT    table1.column, table2.column
FROM      table1, table2
WHERE     table1.column1 = table2.column2;
```

- Write the join condition in the **WHERE** clause.
- Prefix the column name with the table name when the same column name appears in more than one table.

# Qualifying Ambiguous Column Names

- **Use table prefixes to qualify column names that are in multiple tables.**
- **Improve performance by using table prefixes.**
- **Distinguish columns that have identical names but reside in different tables by using column aliases.**

# Using Table Aliases

- Simplify queries by using table aliases.
- Improve performance by using table prefixes.

```
SELECT e.employee_id, e.last_name, e.department_id,  
       d.department_id, d.location_id

# Practice 4, Part One: Overview

**This practice covers writing queries to join tables together using Oracle syntax.**

# Joining Tables Using SQL: 1999 Syntax

Use a join to query data from more than one table.

```
SELECT    table1.column, table2.column
FROM      table1
[CROSS JOIN table2] |
[NATURAL JOIN table2] |
[JOIN table2 USING (column_name)] |
[JOIN table2
    ON(table1.column_name = table2.column_name)] |
[LEFT|RIGHT|FULL OUTER JOIN table2
    ON (table1.column_name = table2.column_name)] ;
```

# Creating Cross Joins

- The **CROSS JOIN** clause produces the cross-product of two tables.
- This is the same as a Cartesian product between the two tables.

```
SELECT last_name, department_name  
FROM   employees  
CROSS JOIN departments ;
```

LAST_NAME	DEPARTMENT_NAME
King	Administration
Kochhar	Administration
De Haan	Administration
Hunold	Administration

160 rows selected.

# Creating Natural Joins

- The **NATURAL JOIN** clause is based on all columns in the two tables that have the same name.
- It selects rows from the two tables that have equal values in all matched columns.
- If the columns having the same names have different data types, an error is returned.

# Retrieving Records with Natural Joins

```
SELECT department_id, department_name,  
       location_id, city  
FROM   departments  
NATURAL JOIN locations ;
```

DEPARTMENT_ID	DEPARTMENT_NAME	LOCATION_ID	CITY
60	IT	1400	Southlake
50	Shipping	1500	South San Francisco
10	Administration	1700	Seattle
90	Executive	1700	Seattle
110	Accounting	1700	Seattle
190	Contracting	1700	Seattle
20	Marketing	1800	Toronto
80	Sales	2500	Oxford

8 rows selected.

# Creating Joins with the USING Clause

- If several columns have the same names but the data types do not match, the `NATURAL JOIN` clause can be modified with the `USING` clause to specify the columns that should be used for an equijoin.
- Use the `USING` clause to match only one column when more than one column matches.
- Do not use a table name or alias in the referenced columns.
- The `NATURAL JOIN` and `USING` clauses are mutually exclusive.

# Retrieving Records with the USING Clause

```
SELECT e.employee_id, e.last_name, d.location_id
FROM   employees e JOIN departments d
      USING (department_id) ;
```

EMPLOYEE_ID	LAST_NAME	LOCATION_ID
200	Whalen	1700
201	Hartstein	1800
202	Fay	1800
124	Mourgos	1500
141	Rajs	1500
142	Davies	1500
143	Matos	1500
144	Vargas	1500
103	Hunold	1400

19 rows selected.

# Creating Joins with the ON Clause

- The join condition for the natural join is basically an equijoin of all columns with the same name.
- To specify arbitrary conditions or specify columns to join, the ON clause is used.
- The join condition is separated from other *search* conditions.
- The ON clause makes code easy to understand.

# Retrieving Records with the ON Clause

```
SELECT e.employee_id, e.last_name, e.department_id,  
       d.department_id, d.location_id  
FROM   employees e JOIN departments d  
ON      (e.department_id = d.department_id);
```

...

# Creating Three-Way Joins with the ON Clause

```
SELECT employee_id, city, department_name
FROM   employees e
JOIN    departments d
ON      d.department_id = e.department_id
JOIN    locations l
ON      d.location_id = l.location_id;
```

# INNER Versus OUTER Joins

- In SQL: 1999, the join of two tables returning only matched rows is an inner join.
- A join between two tables that returns the results of the inner join as well as unmatched rows left (or right) tables is a left (or right) outer join.
- A join between two tables that returns the results of an inner join as well as the results of a left and right join is a full outer join.

# LEFT OUTER JOIN

```
SELECT e.last_name, e.department_id, d.department_name
